Lists

```

1 data List [a] = [] | (:) a [a]
2
3 — or ...
4 data List a where
5     Empty :: List a
6     Cons  :: a -> List a -> List a

```

Lists in **Haskell** are a persistent data structure, meaning that when operations are applied to lists the original list is maintained (not mutated).

Append

We can append lists, by traversing over the first list, copying values (this ensures both argument lists are preserved).

```

1 (++) :: [a] -> [a] -> [a]
2 []   ++ ys = ys
3 (x:xs) ++ ys = x:(xs ++ ys)

```

As the entire first list must be traversed, the cost of $xs++ys$ is $T_{(++)}(n) \in O(n)$ where $n = \text{length } xs$

Foldr

```
1 foldr :: (a -> b -> b) -> b -> [a] -> b
2 foldr f k [] = k
3 foldr f k (x:xs) = f x (foldr f k xs)
```

As you can see, $\text{foldr } (:) [] \equiv \text{id}$.

Foldr can also be expressed through bracketing

$$\text{foldr } f \ k \ [x_1, x_2, \dots, x_n] \equiv f \ x_1 \ (f \ x_2 \ (\dots (f \ x_n \ k) \dots))$$

Associativity

Associativity determines how operations are grouped in the absence of brackets.

$a \spadesuit b \spadesuit c$ unbracketed statement
 $((a) \spadesuit b) \spadesuit c$ \spadesuit is left associative
 $a \spadesuit (b \spadesuit (c))$ \spadesuit is right associative

If \spadesuit is associative, then the right & left associative versions are equivalent.

foldr applies functions in a right-associative scheme.

Foldl

```
1 foldl :: (b -> a -> b) -> b -> [a] -> b
2 foldl f k [] = k
3 foldl f k (x:xs) = foldl f (f k x) xs
```

As you can see $\text{foldl} (\text{snoc}) [] \equiv \text{id}$.
Foldl can be expressed through bracketing

$$\text{foldl } f \ k \ [x_1, x_2, \dots, x_n] \equiv f \ (\dots (f \ (f \ k \ x_1) x_2) \dots x_n)$$

Monoids

Consider the case when for some \star and ϵ : $\text{foldr } \star \ \epsilon \equiv \text{foldl } \star \ \epsilon$. For this to be possible for $\star :: a \rightarrow a \rightarrow a$ and $\epsilon :: a$.

$$\begin{array}{ll} \star \text{ must be associative} & x \star (y \star z) \equiv (x \star y) \star z \\ \epsilon \text{ must have no effect} & \epsilon \star n = n \end{array}$$

These properties for a **monoid** (a, \star, ϵ) .

Other example include:

$$\begin{array}{llll} (\text{lists}, ++, []) & (\mathbb{N}, +, 0) & (\mathbb{N}, \times, 1) & (\text{bool}, \wedge, \text{true}) \\ (\text{bool}, \vee, \text{false}) & (\mathbb{R}, \max, \infty) & (\mathbb{R}, \min, -\infty) & (\text{Universal set}, \cup, \emptyset) \end{array}$$

We can also find monoids of functions:

$$(a \rightarrow a, (.), \text{id})$$

as $(\text{id} \cdot g)x \equiv \text{id}(g \ x)$ and $((f \cdot g) \cdot h)x = f(g(h \ x))$

Concat

We can easily define concat recursively as:

```
1 concat :: [[a]] -> [a]
2 concat [] = []
3 concat (xs:xss) = xs ++ concat xss
```

We can also notice that $([[a]], (++) , [])$ is a monoid, so we can use **foldr** or **foldl**

```
1 concatr :: [[a]] -> [a]
2 concatr = foldr (++) []
```

```
1 concatr :: [[a]] -> [a]
2 concatr = foldl (++) []
```

as `(++)` makes a copy of the first argument (to ensure persistent data), if we apply it in a left associative bracketing scheme we will have to make larger & larger copies.

$$(\dots(((([] ++_0 xs_1) ++_m xs_2) ++_{2m} xs_3) ++_{3m} xs_4 \dots) ++_{mn} xs_n$$

Hence where $n = \text{length } xs$ and $m = \text{length } xs_1 = \text{length } xs_2 = \dots = \text{length } xs_n$.

$$\begin{aligned} T_{concatl}(m, n) &\in O(n^2 m) \\ T_{concatr}(m, n) &\in O(nm) \end{aligned}$$

DLists

Instead of storing a list, we store a composition of functions that build up a list.

$$\begin{aligned} &xs_1 ++ xs_2 ++ xs_3 ++ \dots ++ xs_n \\ &\quad \downarrow \\ &f\ xs_1 \bullet f\ xs_2 \bullet f\ xs_3 \bullet \dots \bullet f\ xs_n \\ &\quad \downarrow \\ &(xs_1 ++) \bullet (xs_2 ++) \bullet (xs_3 ++) \bullet \dots \bullet (xs_n ++) \end{aligned}$$

We can then apply this function on the empty list `[]` to get the resulting list.

```

1  newtype DList a = DList ([a] -> [a])
2
3  instance List DList where
4      toList :: DList a -> [a]
5      toList (DList fxs) = fxs []
6
7      fromList :: [a] -> DList a
8      fromList xs = DList (xs++)
9
10     (++) :: DList a -> DList a -> DList a
11     DList fxs ++ DList fys = DList (fxs . fys)

```

We can form a **monoid** of $(DList, ++, DList\ id)$.
